ACKNOWLEDGEMENTS

We wish to thank all those who contributed to this study and final report. This survey and final report would not have been possible without them. We especially would like to thank:

- Jacqueline Waggoner, Nursing Care Act Coordinator and the Committee on Nursing of the Illinois Department of Professional Regulation for their input into the survey design and support throughout the project.
- The College of Nursing at the University of Illinois at Chicago's Peoria Regional Site who generously provided us budgeting and secretarial support. A special thank you to Dr. Norma Kelly, Patricia Furnace, Karen Minter, and Nylene Bradburn.
- Dr. Lucy Marion, Department Chair of Public Health, Mental Health, and Administrative Studies in Nursing at the College's Chicago campus who provided both material and much needed moral support throughout this project.
- Dr. Donna Hartweg, Director, Illinois Wesleyan University School of Nursing and the IWU faculty for their support and encouragement.
- Dr. Judith Cooksey, Director, Illinois Center for Health Workforce Studies, University of Illinois at Chicago, for her financial support, national contacts, thoughtful questioning-- and a much needed computer. The Center is funded by a grant from the Health Resources and Services Administration, Bureau of Health Professions.
- The University of Illinois College of Medicine who provided research office space. A special thank you to Virginia Robertson of the College of Medicine security staff who opened thousands of survey envelopes.
- Kimberly Bankston, Patricia Eathington, Shellene Coleman, and Lorna Finnegan, the research assistants without whom this survey and report would not have been possible.
- Leslie Schenkel, whose expertise in typing and formatting the final copy were invaluable.

Finally, we would like to add a special note of thanks to all of the registered nurses licensed in Illinois who responded to the survey questionnaire. Your input will prove invaluable to those who use this report in planning for health manpower and services in Illinois.

EXECUTIVE SUMMARY

The Year 2000 Survey of Registered Nurses in Illinois reported within these pages is the seventh such study since 1986. The 2000 survey report presents information on all RNs registered in Illinois, but focuses primarily on those currently working in the state. A final chapter of this report provides information on the advanced practice nurse workforce in the state.

The Year 2000 Survey was conducted by the College of Nursing at the University of Illinois at Chicago, Peoria regional site (UIC), in cooperation with the Illinois Wesleyan University School of Nursing and under contract with the Illinois Department of Professional Regulation (IDPR). As of June 1, 2000, IDPR reported that the total number of RNs actively licensed in Illinois was 142,408. This is an increase of 4.8% from 1996 figures. This increase compares to an increase of 16.7% between 1992 and 1996 and a 6.8% increase between 1988 and 1992. The dramatic decline between 1996 and 2000 after a sharp rise in the early 90's parallels national data.

Approximately 83% of registered nurses living in Illinois are working-- a significant decline from 1996. Within this group, full time employment has reached an all time high (73%), up from a 1996 rate of 66%. Also, there has been a dramatic change in employment status of those RNs who report having more than one job--an increase of 9.2% since 1996. Of the unemployed workforce, approximately 17%, the largest percentage (40%) is retired. Only 7.5% of unemployed RNs are actively seeking employment.

Of RNs employed in Illinois, most live and work in the state (93.4%) and were employed in nursing two years ago (94%). Six major employment settings were identified for RNs: hospitals, nursing homes, clinics, private/group medical practices, home health care and community/public health settings. Hospitals remain the predominate employers: 58% of nurses work in that setting. This finding is consistent with The National Sample of Registered Nurses March 2000 preliminary report (2001) that described 58% of registered nurses as employed in hospitals. For this survey, nurses were asked to select one category that best described their clinical practice specialty. Almost 23% of nurses described their specialty as critical care/emergency room/operating room. Most nurses continue to hold job titles that suggest a direct patient care position, approximately 56% are staff nurses; however, since 1996 nurses holding positions with administrative and educative functions has increased. Approximately 25% of nurses held some type of national specialty certification.

Following a trend identified in previous Illinois surveys and national surveys the Illinois registered nurse workforce is increasing in experience as well as age. In the 2000 survey, 51.9% of RNs reported more than 15 years of experience, slightly higher than the 50.8% reported in 1996. The portion of RNs with 1-5 years experience increased 2.5% over the last four years, but is still approximately 3% less than reported in 1988.

Direct patient care activities comprise 62.4% of the RN's workweek; this is similar to 1996 findings. Nurses employed in hospitals, private/group medical practices, and clinics spend more time in direct patient care. Direct patient care activities, as a portion of the workweek, rose approximately 5% for RNs employed in hospitals. Nursing-related non-patient care activities during the workweek were the highest for mental health and community health nurses.

When queried about significant factors affecting job selection, 65% of nurses identified selecting their current position because they desired a specific experience or specialization. Work schedule, a work environment factor that can be controlled by the employer, was chosen by 55% of RNs as a determinant of job selection. The majority (75%) of RNs indicated they would be willing to work more hours; for most the primary incentive was increased salary.

Nurse's salaries in Illinois continue to have a narrow range with 85% of all salaries falling between \$25,001 and \$75,000. The median salary range for RNs is \$35,001-\$50,000. Office nurses reported the lowest salaries while nurse anesthetists reported the highest. Slightly over one-half of nurse anesthetists earn between \$100,001-\$150,000 annually. Over one-third of nurses related some degree of dissatisfaction with their nursing salary; staff nurses were the most dissatisfied.

Overall, nurses are satisfied (83.9%) with their primary nursing position. Advanced practice nurses are most satisfied with their nursing position and staff nurses are the most dissatisfied. Gender differences were minimal with males being slightly less dissatisfied with their nursing position than females. When racial background was explored, white non-Hispanics indicated the highest degree of satisfaction (86.1%) with their nursing position. Minorities were less satisfied with their nursing positions. In particular, the percentage of African Americans who reported satisfaction was 76.6%. How satisfied RNs are with their primary nursing position tends to increase with age.

Although more nurses report associate degrees as their initial level of education (37.9%), more nurses report baccalaureate degrees as their highest level of education (39.4%). Levels of education vary widely across the state. The percentage of nurses educated originally at the baccalaureate level or above ranges from highs of approximately 50% in some areas of the state to lows of 10% in other areas. The percentage of nurses whose highest level of educational attainment is a baccalaureate degree or above also varies greatly, from lows of approximately 25% to highs of 66%. Cook and DuPage counties have the highest concentrations of baccalaureate and master's prepared nurses. Proportionately males have more education than their female counterparts. Across all age groups and regardless of number of children, the baccalaureate degree is the most frequently reported highest degree attained. Approximately 50% of nurses in most practice specialties are educated the baccalaureate level or higher.

Satisfaction with position does not appear to vary greatly by basic educational program or by highest educational degree attained. Associate degree graduates report the lowest levels of satisfaction; master's and doctorally prepared RNs report the highest. Regardless of basic educational program or highest level of educational attainment, the majority of nurses are satisfied with their salaries. However, nurses with the highest levels of education are approximately twice as likely as their less educated counterparts to report high levels of satisfaction with salaries.

The percentage of RNs enrolled in a formal academic degree program has continued to decline gradually from a high of 13.7% in 1986 to the current rate of 9.6%. This rate shows little variance by geographic area. However, rates of enrollment vary widely by primary nursing position, clinical specialty, and employment setting. A slight majority of those returning to school for a formal degree are seeking a baccalaureate (56.4%); another 38.6% are seeking a master's.

The proportion of RNs participating in continuing education has remained fairly consistent between 1996 and 2000 at approximately 89%. The majority of these RNs report less than 20 hours of such education in the past year. Although continuing education participation varies little by geographic area, participation does vary widely by primary nursing position, clinical specialty, and employment setting.

Currently of all RNs licensed in Illinois, approximately 7.7% were educated as advanced practice nurses (APNs) and 7.3% are currently practicing as APNs. The majority of those practicing as APNs are nurse practitioners (45.0%). Over two-thirds of the APN workforce is master's prepared and approximately 50% report five or less years of experience in that role.

For the first time in these Illinois RN surveys, specific information was collected on advanced practice nurses. The researchers recognized the importance of gathering baseline information on this group before the implementation of recent Illinois licensure changes. In future years as the climate for APN practice changes, it will be interesting to follow employment trends in this critical segment of the RN workforce.

CHAPTER 1

INTRODUCTION

The Year 2000 Survey of Registered Nurses in Illinois reported within these pages is the seventh such study since 1986. The purpose of such surveys is to provide current, accurate information on the Illinois registered nurse (RN) workforce that can be used in developing health care policy and planning within the state. Between the years of 1986 and 1996, this survey was conducted every two years. However, in the mid 1990s, the legislature mandated a four-year survey cycle. The 2000 survey report presents information on all registered nurses (RNs) licensed by the state of Illinois, but focuses primarily on those currently working in the state. Information on the demographics, labor activity, practice patterns, and educational patterns of the workforce are presented. A final chapter of this report provides information on the advanced practice nurse (APN) workforce in the state.

The Year 2000 Survey was conducted by the College of Nursing at the University of Illinois at Chicago, Peoria regional site (UIC), in cooperation with the Illinois Wesleyan University School of Nursing and under contract with the Illinois Department of Professional Regulation (IDPR). UIC has conducted such surveys for IDPR since 1986.

Method

As of June 1, 2000, IDPR reported that the total number of RNs actively licensed in Illinois was 142,408. Because of the timing of the IDPR contract offer, this survey was not sent to every registered nurse with license renewal materials. Rather, IDPR provided the researchers with a list of all RNs actively licensed in Illinois on June 1, 2000. From this list, the researchers drew a random sample of 14,972 subjects.

In an effort to improve on the low return rate of the 1996 survey, three changes in method were made: (1) two follow-up mailings to study participants who did not respond to prior mailings, (2) a shortened survey instrument, and (3) a clearer format that was more easily completed than the previous Scantron format.

The research methodology and survey instrument were reviewed by the institutional review boards of the University of Illinois at Chicago and Illinois Wesleyan University. These boards are responsible for determining if any research risks exist to study participants. Both boards found the research presented no risks to participants.

Sample. Of the 14,972 mailed surveys, six hundred forty-two (4.8%) were returned because of incorrect addresses or subject was deceased. Eleven unusable survey questionnaires were deleted from the data set. These survey questionnaires were either duplicates or blank. The total final sample consisted of 9354 surveys for a response rate of 62.5%. Survey research experts consider this a good response rate for mailed surveys (Aday, 1996).

As in past reports, the reader may obtain a rough estimation of the actual number of RNs registered in Illinois who represent a specific characteristic. Results are reported by percentages. These percentages may be multiplied times 142,408 to obtain population

estimates. For example, 82.1% of subjects reported current employment in nursing: $.821 \times 142,408 =$ an estimated 116,917. Use this rough estimate with caution, however. It assumes that all RNs responded to every question at the same rate, without bias, as they would have responded to the total survey questionnaire. This assumption most likely does not hold for all questions, particularly sensitive questions such as those about income and race/ethnicity.

To compare the distribution of this sample to those of prior surveys, the research team examined the geographic distribution by Health Service Area (HSA) across the seven surveys done since 1986. These HSAs are graphically depicted on a map of Illinois found in Appendix A. The results of this comparison are presented in Table 1.1. As anticipated, the percentage of respondents reporting residence outside Illinois is greater than that reported in 1996. In that year, the survey response rate was particularly low and a sampling bias was introduced because of the type of convenience sampling done. However, the number of RNs reporting residence outside Illinois in 2000 is still significantly less than that found in 1986-1994. The fact that surveys were not mailed to subjects with official licensure renewal may have reduced the response rate of out of state nurses. Or, because the 2000 sample was the first random sample with follow-up, the Year 2000 figures may be the more accurate. It is of note, however, that the number of nurses employed in nursing outside of Illinois as a proportion of Year 2000 Survey returns increased with each successive mailing.

TABLE 1.1

PERCENTAGE OF SURVEYED RNS BY RESIDENTIAL HSA FROM 1986-2000

Residential HSA	Year of Survey						
	1986	1988	1990	1992	1994	1996	2000
HSA 1	5.0	6.7	5.3	5.3	4.5	6.1	5.4
HSA 2	6.5	8.0	6.3	6.5	7.0	7.5	7.5
HSA 3	4.9	6.4	5.2	5.4	6.2	6.0	6.4
HSA 4	6.1	7.6	5.8	6.0	6.3	6.8	5.5
HSA 5	3.5	5.1	3.9	4.4	5.0	5.4	5.4

HSA 8	7.4	10.2	8.2	8.8	8.7	10.0	10.7
HSA 9	4.2	5.9	4.8	5.1	5.2	6.3	6.7
HSA 10	2.0	2.6	1.9	1.2	2.0	2.1	2.1
HSA 11	3.9	4.6	3.7	3.9	3.8	4.4	4.1
Other USA	12.9	17.4	10.8	13.1	13.1	3.2	7.1

The Survey Instrument. The instrument for the Year 2000 survey was shortened from the 1996 survey and reflects selected questions from the 1996 Illinois survey and the 1996 National Sample Survey of Registered Nurses. Researchers chose questions that allowed critical comparisons not only with past Illinois survey data, but also with national data. After review and modification of the content of the survey instrument by national experts in nurse and health care workforce studies, the researchers sent the instrument to the UIC Survey Research Laboratory for a critique of format.

After minor modifications, the instrument was then presented to the Illinois Committee on Nursing and a representative of the Illinois Nurses Association in May of 2000. This committee requested two minor revisions. A copy of the instrument is included in Appendix B.

Data Collection. The UIC research team received completed questionnaires from July through December of 2000. Trained professional data entry personnel entered data in a two-step process designed to ensure 99.5% accuracy. A small random sample of the data set was also compared to the paper surveys. The accuracy rate was 99.9985%.

Data Analysis. Data were converted from Microsoft Excel format to Statistical Package for the Social Sciences (SPSS) Version 9 format for analysis. Two distinct data sets were formed to examine the data. The first set consists of all 9354 useable surveys and represents all nurses licensed in Illinois regardless of employment status or state of residence. A subset of this first set is used throughout the majority of the report and consists of the 6752 licensed registered nurses who were working in Illinois in summer of 2000. Not every subject answered every survey question. Therefore, for example, the number of subjects reporting their income (a fairly sensitive issue) is considerably less than the number reporting their employment status (a less sensitive issue). The authors refer to these differing numbers of subjects throughout the report and where appropriate, the number of subjects from the Year 2000 Survey are included in a note at the bottom of tables.

When the total sample of all nurse or working nurses is examined chances are 99 out of a 100 that the error is no greater than 1%. When subsamples of greater than 400 RNs are subdivided into categories, chances are 95 out of a 100 that the error is no greater than 5%. Therefore, the reader can be confident in the relative accuracy of the interpretation of the large sample segments. Results of smaller sample segments (<400) should be interpreted with caution (e.g., smaller geographic areas, clinical nursing settings with few subjects such as occupational health).

Finally, when comparisons are made to previous Illinois surveys, the reader is referred to Appendix D to find the specific citations for these surveys. Comparisons with national data are from the 1997 and 2001 Health Resources and Services Administration national surveys—also referenced in Appendix D.

Organization of the Report

Because of the great amount of data gathered in the Year 2000 survey, several different types of analysis on a variety of workforce topics was possible. The overall organization of the report has been kept similar to that of the 1996 report to aid readers making comparisons. Succeeding chapters provide an overview of the workforce (Chapter 2), and address labor force activity (Chapter 3), practice patterns (Chapter 4), and educational patterns of the registered nurse workforce (Chapter 5). However, several charts have been added for ease of data interpretation, the survey instrument and a map and table of Illinois Health Service Areas (HSAs) have been included in an appendix, and a chapter describing APN practice patterns (Chapter 6) has been added.

CHAPTER 2

OVERVIEW OF REGISTERED NURSES LICENSED IN ILLINOIS

This chapter broadly describes registered nurses carrying active licenses in Illinois. This population includes **all** nurses licensed in Illinois regardless of employment status or state of residence. As of June 1, 2000, the total number of RNs actively licensed in Illinois was 142, 408. This is an increase of 4.8% from 1996 figures. This increase compares to an increase of 16.7% between 1992 and 1996 and a 6.8% increase between 1988 and 1992. The dramatic decline between 1996 and 2000 after a sharp rise in the early 90's parallels national data.

Data reported throughout this chapter is based on the sample of 9465 registered nurses with active Illinois licenses who completed the Year 2000 RN survey.

EMPLOYMENT

Table 2.1 lists the reported employment status of RNs licensed in Illinois. The vast majority (82.1% or an estimated 116,917) are employed in nursing. This number has decreased from highs of 88%-90% in surveys conducted from 1990-1996 and parallels current national figures. Prior to 1990, nursing employment was more similar to the current rate: 81% in 1986 and 84% in 1988.

A small percentage (5.2%) of nurses are employed both in and outside of nursing and 17.8% of nurses report working in two nursing positions. Table 2.2 further describes those nurses licensed in Illinois who are not presently working. The largest percentage of unemployed nurses are retired (39.7%). Only 7.5% are seeking employment. A slightly larger percentage (5.7%) are employed outside nursing.

Nurses licensed in Illinois have an average of 16.8 years of experience in nursing and an average of 8.9 years with their current employer. These averages are comparable to those found in the 1996 study. Comparisons of years of experience with prior surveys are presented in Table 2.3. From the 1980's there has been a steady decline in the proportion of nurses reporting one to five years of employment in nursing. In 1986, 34.4% of nurses had 1-5 years of experience; in 2000, that percentage was 17.7%. A corresponding increase in the number of nurses reporting 21-35 years of experience has occurred -- from 12.8% to 30.7%.

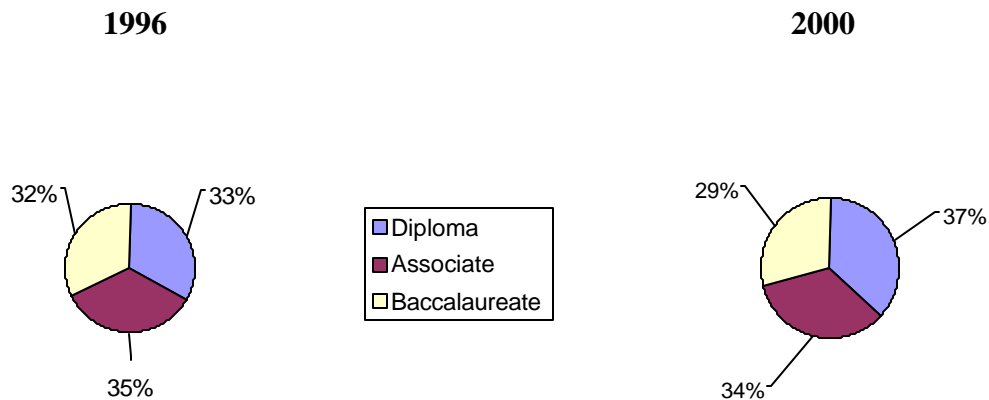

Certification. Across nursing specialties approximately 23.4 % of nurses living in Illinois held some type of national specialty certification (Table 2.4). School nurses and those nurses employed in adult primary care report the highest levels of certification -- 36.7% and 28.5%, respectively. Public health (12.2%) and geriatric nurses (14.0%) report the lowest levels of certification. Certification is gaining prominence as research studies support the positive relationship between certification and patient outcomes.

Education

Initial Education. The type of basic nursing education program reported by RNs has changed substantially since 1996 (Figure 2.1). While the proportion of associate degree graduates has remained relatively stable, the proportion of diploma graduates has decreased by approximately 5% and the proportion of baccalaureate graduates has increased by approximately 3%. Unlike findings in prior surveys, associate degree nurse (ADN) graduates exceeded graduates of both diploma and baccalaureate programs.

Figure 2.1

Initial Education: 1996 and 2000

Highest Degree Attained. Over the past 14 years, several changes in highest level of nursing education, which incorporates degrees earned subsequent to initial RN education, have occurred (Figure 2.2). The most striking is the decrease in diploma as highest level of educational attainment. As in 1996, the largest proportion of RNs in 2000 are baccalaureate prepared.

Demographics

Selected demographic information is discussed below and presented in Table 2.5.

Age. This survey reflects the aging of the RN population. The mean age of survey participants in the year 2000 was 45.9 years. The proportion of the workforce 46 years of age and above increased steadily from 1986 to 2000, while the proportion of nurses 30 years and under declined steadily between 1986 and 1996—from a high of 19.9% to 9.0%. The Year 2000 Survey heralded a slight increase in the proportion of RNs 30 years and under and a modest decrease in nurses 31-45 years of age. The current mean age of the RNs licensed in Illinois is approximately one year older than the national average of 45.2 years.

Figure 2.2.

Highest Nursing Education Preparation of Registered Nurse Population: 1988 - 2000

Table 2.6 shows the relationship between mean age and years of experience. Note that among those RNs currently working in Illinois older nurses have more experience. These numbers have been fairly consistent over the time. Although there would appear to be a decrease in the mean age of nurses with 1-5 years of experience since 1996, this figure may be misleading as the Year 2000 survey data includes those working less than one year as well as those reporting working 1-5 years. Note that the proportion of the workforce with 1-5 years of experience, who are the youngest nurses, has declined steadily over the years from 32% in 1988 to 18% in 2000.

Gender, Marital Status, and Children. The RN population licensed in Illinois remains predominantly female (95.9%), married (71.5%), with two or more children (66.3%). The proportion of men among those employed in nursing in Illinois is also 4.1% and is slightly below the national figure of 5.9%.

Racial/Ethnic Background. The vast majority of RNs continue to be white non-Hispanic (84.3%). However, the proportion of those from other racial/ethnic backgrounds has increased by 6% since 1996 (Table 2.4). Nationally, white non-Hispanic nurses represent 86.6% of the total nursing workforce, but just 71.8% of the U.S. total population.

Gross Household Income. Approximately two-thirds of RNs report a household income of \$50,000 or more. This proportion has approximately doubled since the late 1980's.

Note. Only those RNs currently practicing were asked to provide years of experience.

CHAPTER 3

EMPLOYMENT ACTIVITY OF REGISTERED PROFESSIONAL NURSES WORKING IN ILLINOIS

Data are presented describing the registered nurses who are employed either full time or part time in nursing in the state of Illinois. Following this information a brief description of RNs who are not employed and those who are employed outside nursing but continue to maintain an Illinois RN license is provided. Information for each Health Service Area (HSA) in Illinois is presented in tables at the end of the chapter.

RNs Employed in Illinois in Nursing

From the original sample of nurses licensed in the state of Illinois, 72 %, or 6752 registered nurses reported being employed in nursing Illinois during June 2000. Most (93.5%) reported living and working in Illinois. The others either work in Illinois and live in a neighboring state (2%) or did not report where they lived (4%). These data are consistent with that of the sixth survey done in 1996.

About 94% of RNs who reported being employed in nursing two years ago also reported being employed in nursing in 2000. Of those not reporting employment two years ago about 5% were not licensed; 1% were licensed and not working in nursing. Table 3.1 shows the distribution of registered nurses reporting employment in 1996 and 2000 by the Health Service Area of employment. Modest increases in the nursing workforce were reported in HSAs 5, 8, and 9.

Primary Employment Setting. Six major employment settings were identified for RNs: hospitals, nursing homes, clinics, private/group medical practices, home health care agencies, and community public health settings (See Table 3.2).

The predominate employment setting remains within the hospital. The twelve-year trend in decline in hospital employment in Illinois appears to have stopped with an increase 4% in 2000. However, this reversal of trend could be due to changes in reporting. In previous Illinois surveys hospital clinics were reported as a separate setting. In the current survey approximately 58% of nurses reported employment in the hospital setting. This finding is consistent with preliminary data from the National Sample Survey of Registered Nurses (2000) that found 59% of registered nurses worked in hospital settings.

The percentage of nurses employed in home health care agencies declined over 2%, the first decline in that area since the survey has been conducted. This decline may reflect recent changes in regulation of home care agencies. Ambulatory setting, including clinics and private/group medical practices, experienced gains during the past four years. The remaining RNs employed in nursing in Illinois reported working in such areas as nursing education, public/private schools, occupational health, managed care/insurance, nursing pools, and self-employment (See Table 3.3).

Clinical Practice Specialty. Due to changes in reporting clinical practice specialty throughout the past several state surveys, comparisons should be viewed

carefully. In this survey respondents were asked to select one primary clinical practice specialty; each category was mutually exclusive. Past surveys permitted RNs to select more than one specialty area. Over one-fifth of the RNs reported critical care/ER/OR as their primary clinical practice specialty. The next most selected practice area was other (20.7%), followed by medical-surgical nursing (14.1%). No other practice area was designated by more than 9% of RNs (Table 3.4).

New categories added for 2000 were for critical care, school nursing, primary care, and general; these may have been responsible for the reduction in the percent of RNs selecting “other”, which declined from 35% in 1996 to 20.7% in 2000. The aggregated data from 1996 shows that when one specialty was selected, 20.6% of registered nurses identified themselves as medical or surgical nurses--approximately 6% more than in 2000. Many of the 1996 respondents who selected medical or surgical nursing may have been practicing in critical care areas. Nurses identifying their practice area as obstetrics/gynecology increased slightly from 8.9% in 1996 to 10.1% in 2000. There was a decline in pediatric clinical practice from 7.8% to 5.7%. A copy of the specialty areas reported in 1996 is included in the Appendix C for your convenience.

Another view of practice specialty, setting by specialty, is shown in Table 3.5. As expected the majority of critical care/ER/OR nurses practice in hospitals (93%) and most public health nurses (64%) practice in community/public health settings. Those RNs who described their clinical specialty as other are employed in the following settings: hospital (44%), clinics (11%), private/group medical practice (10%), and home health (8%). The

above gives some indication of the work of RNs who reported no clinical practice specialty. Data for specific HSAs can be found in Table 3.3.

Primary Nursing Position. Five position titles comprise over 85% of all RNs working in Illinois: staff nurse (55.6%), nurse manager (8.4%), office nurse (8.3%), case manager (4.5%) and other (10.6%) (Table 3.6). Due to changes in title categories determination of exact trends is not possible. When combining titles into broad categories of administration, patient care, education, and other, comparisons can be made with the 1996 data. Most nurses continue to hold job titles that suggest a patient care position; however, during the four years nurse’s positions in administration, education, and other experienced increases. Data for specific HSAs can be found in Table 3.7.

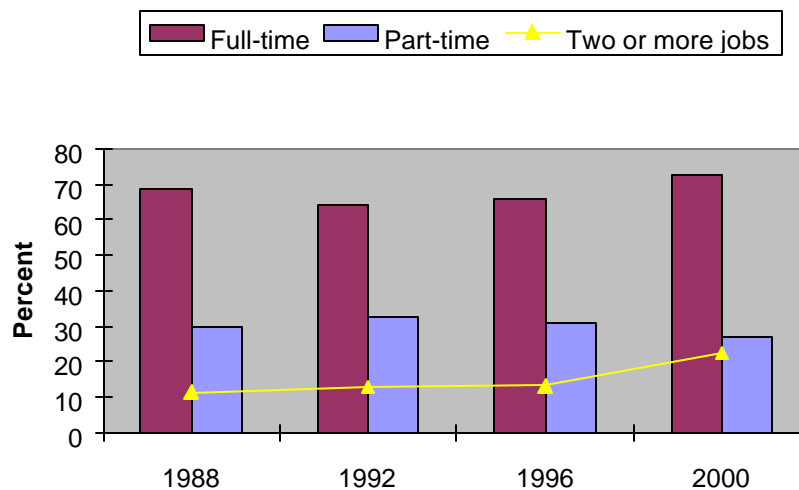

RNs whose primary position is case manager, a relatively new position and one not reported in 1996, are employed principally by hospitals (28%), managed care/insurance agencies (21%), home health agencies (18%), and community/public health facilities (15%).

Distance to Work. The majority of RNs live geographically close to their place of employment. Many (75%) travel approximately 18 miles one-way to their job. Distance to work is not much further in the rural areas of the state (HSAs 5 and 3, respectively 14.2 miles and 14.5 miles) than in the greater Chicago area (HSAs 6, 7, and 8) where travel time per mile is substantially increased. Actually, HSA 6 (Chicago) reported the furthest distance to work, 15.5 miles. Data for specific HSAs can be found in Table 3.8.

Employment Status of RNs Working in Illinois. The data on the employment status of working RNs tends to fluctuate, but full time employment has reached an all time high in Illinois with 72.8 % of RNs responding they work full time. In 1996 66% of RNs indicated they worked full time. This full time employment is reflected in the percentage of RNs reporting they worked part-time (27%), a drop of 4% since 1996. Findings from the 1996 National Sample Survey of Registered Nurses stated 29% of RNs were employed part time. However, the most dramatic change in employment status is those RNs who report having more than one job --an increase of 9.2% since 1996 (Table 3. 9). We have defined full-time work as 32 or more hours per week in this survey.

Figure 3.1

Employment Status of RNs Working in Illinois

N = 6752

An examination of the demographic characteristics between RNs employed full time and those employed part-time suggests that the typical full time employed RN is: female, 46-55 years old, white non-Hispanic, married, with two children, and lives in a household with an income between \$50,001 and \$75,000. Similarly, the typical RN employed on a part-time basis is female, 31-45 years old, white non-Hispanic, married, with three or more children, and lives in a household with an income between \$50,001 and \$75,000.

Employment Status and Primary Setting. The portion of the nurse supply working full time in a primary setting ranged from 86.3% in managed care/insurance facilities to 33.3% in nursing pools (Table 3.10). Hospitals, the primary setting employing the highest percentage of RNs, employs approximately 74% of RNs on a full-time basis and 26% part-time. This is an increase in full-time hospital employment of 16.5 % since 1996. RNs employed in less structured settings, nursing pools, private/group medical practice, and self-employed are less likely to be in employed full

time. Those employed in nursing pools and public/private schools are most likely to hold more than one job.

The home care industry, which has shown a job growth pattern for the past decade experienced a decline in the percentage of RNs working, but a modest gain (3%) in full-time RNs since 1996. The percentage of RNs employed full time declined in nursing education and community/public health settings.

Employment Status and Nursing Position. The portion of the RN workforce employed full time by nursing position ranged from 55.5% for office nurses to 95.6% for nurse executives. Nurse executives and managers are almost exclusively in full-time positions. Office nurses, faculty, and consultants have the lowest portion of full-time positions (Table 3.11).

Following the Illinois trend toward fuller employment of RNs, almost all positions saw an increase in nurses working full time since 1996. There were three exceptions, full time employment of faculty, clinical nurse specialists, and staff/patient educators declined respectively by approximately 8.6%, 5.6%, and 6.8%.

Employment Status and HSA. All HSAs saw an increase in the percentage of RNs working full time (Table 3.12). As was true in the past several surveys, the southern most HSA (5) continues to maintain over 80% full time employment. However, the Chicago suburban and outlying areas (HSAs 7, 8, and 9) all experienced at least 10% gains in RNs reporting full-time employment. HSA 2 had the smallest gain in full-time employment.

Employment of RNs in More Than One Position. The percentage of Illinois RNs working at more than one job appears to be increasing. Slightly over 22% of nurses indicated they held more than one job. Of those, 17.3% reported the second job was in nursing and an additional 5% maintained employment outside of nursing. While it is predictable that more nurses working part time would also have another position, the differences are not as great as expected. Of nurses working part time, 25.7% hold another position; of nurses working full time, 20.9% report holding another position. Nurse midwives (33.4%) and nurse anesthetists (32.8%) most frequently reported holding more than one job. Frequency of a second position declines with increasing age, female gender, and being married.

Demographic Data. The demographic data of employed registered nurses by their work activity are provided on Table 3.13. Men in nursing are much more likely to hold full time employment compared to women (90.8% and 71.9% respectively) and are more likely to hold more than one job (34.9% and 21.7%, respectively). RNs reporting the highest rates of full-time employment are those under 30 years (84.6%) and those between 46-65 years (75.7%). The mean age for all RNs employed in nursing was 44 years. Nurses employed part-time were slightly older (44.8 years) than those employed full-time (43.8 years).

Least represented in full-time employment are white non-Hispanics (69.8%). All other races report over 77% of respondents employed full time. Over 90% of Asian/Pacific Islanders hold full-time positions. Single nurses are more likely to hold

full-time positions (90.8%) than those married (84.9%) or divorced, widowed, or separated (84.9%).

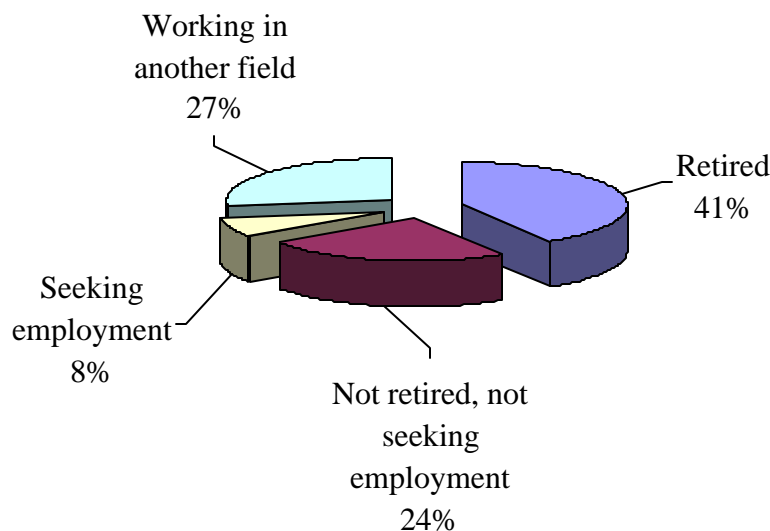

RNs Not Employed in Nursing

Of all RNs licensed in Illinois 17.9% are not employed in nursing. Of those RNs licensed and residing in Illinois, this number is slightly lower, 16.7%. This percentage represents an increase of 6% from 1996 survey levels of unemployment (Table 3.14). The lowest percentages of unemployment in nursing existed in the early 1990s. These Illinois trends parallel those of the nation.

Among unemployed RNs, the largest percentage are retired (41%) (Figure 3.2). Although not retired, another 24% are not seeking employment. Twenty-seven percent are working in another field, and only a small proportion (7%) is actively seeking employment.

Figure 3.2

Lack of Participation in the RN Workforce

N=1621

Specific reasons for lack of participation in the workforce are listed in Table 3.15. Reached retirement age and parenting responsibilities were the two reasons cited most frequently.

Of those RNs residing in Illinois who are not currently working, 34.7% were licensed and working in nursing 2 years ago. However, approximately 36.0% were licensed, but not working in nursing 2 years ago and another 29.2% were neither licensed

nor employed 2 years ago. Approximately 5.8% of currently unemployed nurses have been educated as advanced practice nurses (APNs).

Table 3.16 presents lack of RN labor activity by location of residence. HSAs 3 and 8, the western central region and the northeastern corner of Illinois have the highest proportions of RNs not working in nursing (20.4% and 19.8%, respectively). HSA 6, the city of Chicago, has the lowest (11.5%). In 1996 HSA 8 reported the highest proportion of RNs unemployed in nursing and HSA 6 the lowest.

Lack of labor activity among registered nurses is proportionately highest among 1) females, 2) nurses over 65 years of age, 3) those who are currently or have been married, and 4) Hispanics and white non-Hispanics (Table 3.17). RNs with three or more children and those with children over the age of 18 years are also more likely than their counterparts with fewer and/or younger children to not work as RNs. Finally, those RNs with gross household incomes of less than \$15,000 or more than \$150,000 are less likely to be employed in nursing.

Table 3.1

Employment Distribution by HSA of RNs Currently Working in Nursing for 1996 and 2000

HSA Employment Location	RN Distribution		
	1996 %	2000 %	% Change
Illinois HSA 1	6.2	5.6	-0.6

CHAPTER 4

PRACTICE PATTERNS AND WORKPLACE ENVIRONMENT OF REGISTERED PROFESSIONAL NURSES WORKING IN ILLINOIS

In contrast to data presented in previous chapters summarizing general employment statistics and demographic characteristics of RNs, this chapter reports employment patterns, practice activities, and job satisfaction of registered nurses working in Illinois. As indicated earlier in the methodology section, the survey questionnaire was revised, in part, to shorten the instrument. Therefore, this chapter is substantially shorter than previous reports that included descriptions of specific patient care activities, time spent in specific patient care activities, fringe benefits, and detailed salary information. Items were added to explore registered nurses' job satisfaction and employment choices (not included in earlier surveys). Data are limited to RNs employed in Illinois.

Employment Patterns

Increasing Experience. Similar to the national trend, the RN workforce in Illinois is increasing in nursing experience as it increases in age. In 2000 over 30% of RNs reported having 21-35 years of nursing experience. (See Figure 4.1)

Figure 4.1

Years of Employment for RNs Working in Illinois

N=6663

This group, the largest portion of the Illinois RN workforce, averages 26 years of nursing experience, has worked for the same employer for 13 years, and is employed primarily at the staff nurse level (41%) in a hospital setting (52%). Most reported working full-time (74%), but 53% plan on retiring in the next ten years. The mean age of this 30% of the nursing work force is 51 years. Those RNs with the least experience, 1-5 years, report an average of 3 years nursing experience, most with the same employer.

Most, are employed as staff nurses in hospitals (68%). The mean age of the least experienced group is 33 years. This comparison emphasizes the trend toward more experienced nurses working in non-hospital settings and seeking alternative positions to staff nursing.

A longitudinal pattern of years of nursing experience since 1988 is depicted in Table 4.1. The proportion of nurses with greater than 20 years experience has sharply increased since 1988. Over one-third of the current workforce has more than 20 years of experience. Between 1996 and 2000 there was a 2.5% increase in the proportion of RNs with 1 –5 years of experience. However, 2000 levels are still slightly below those found in 1988. This suggests that the overall RN supply will decrease over the next decade as the more experienced RNs retire. Additionally, nurses with 11-15 years of experience comprise the smallest pool (14.8%) of experienced RNs currently working, providing yet another indicator that the experienced working nurse force in Illinois will continue to decline.

Geographic Variation. Because years of employment varies throughout the state, some areas will be faced with dwindling RN supplies before others (see Table 4.2). HSAs 10 and 11, the western and southwestern portions of the state have the highest portion of experienced RNs; HSA 10 has the smallest portion of RNs with 1-5 years experience. Cook County (HSA 6) experienced the largest gain (5%) in nurses with 21-35 years experience. The southern most portion of the state, HSA 5, has the smallest portion of nurses with 21-35 years experience. However, this HSA was the only geographic area to suffer a decline in the portion of RNs with 1-5 years of experience.

Experience by Primary Employment Setting. Contrasting patterns in length of employment exist across primary nursing positions. Tables 4.3 and 4.4 show the relationship between years worked in nursing and years spent with current employer by position and setting. Staff nurses, educators, nurse managers, nurse executives, and clinical nurse specialists show patterns of increasing average years with their employer as their reported years in nursing increase. Nurse practitioners, nurse midwives, and nurse anesthetists present a different picture, particularly those with less than 16 years as a nurse. For example, nurse anesthetists within the categories 1-5 years nursing experience, 6-10 years nursing experience, and 11-15 years experience all have been with their current employer approximately 3 years. In part, the limited amount of time with employer may be due to experienced RNs returning to school to seek additional education that then opens new areas of employment.

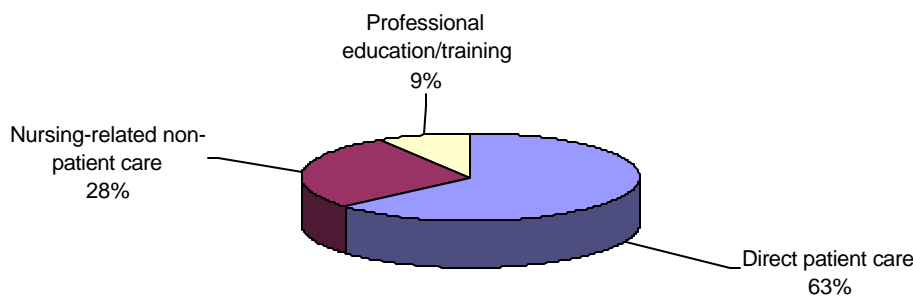

Fewer differences exist when time spent with current employer and in current position are examined by setting. In most settings as years of experience as a nurse increase, there is a corresponding increase in number of years with employer. Nurses in managed care/insurance generally follow the same pattern of increase; however, RNs in this fairly new employment setting have been with their employers for a much shorter time, regardless of years of experience. In two settings, nursing homes and occupational health, there is a drop in the number of years with employer for RNs with over 35 years of experience.

Practice Activities

Activities of Registered Nurses. In 2000 the average percent of time RNs spent in direct patient care activities was approximately 63% (Figure 4.2). As a group, 50% of nurses spent at least 75% of their time in such activities. These findings are similar to the 1996 National Sample Survey of Registered Nurses that found 59.7% of RN time is spent in direct patient care activities and 46% of nurses spent at least 75% of their time in such activities. As could be expected from their primary nursing position title, staff nurse, office nurse, clinical nurse specialist, nurse practitioner, nurse midwife, and nurse anesthetist, this cohort of nurses spends the highest percentage (79%) of their time in direct patient care.

Figure 4.2

Average Percentage of Time in Work Week Spent by RNs in Each Activity

N = 6624

Activities of Registered Nurses by Employment Setting. Table 4.5 depicts the percentage of time RNs in specific employment settings spend in work activities. Those employed in hospitals, private/group practice, and clinics spend the most time in direct patient care, 71.4%, 67.7% and 67% respectively. Of nurses employed in patient care delivery settings those in occupational health and community/public health spend the most time in nursing related non-patient care functions.

Comparisons with 1996 Illinois data should be interpreted with caution since activities were grouped by different categories. However, in the category of “patient care” 78.9% of the 1996 respondents working in hospitals reported spending over 50% of their time in this activity. In the year 2000, 84 % of respondents working in hospitals reported spending over 50% of their time in direct patient care. This increase included time spent in supervision, a category not included in the 2000 survey. Conversely, it may suggest that all nurses, not just staff nurses, working in the hospital are spending more time in direct patient care due to organizational restructuring and a declining pool of RNs.

Activities of Registered Nurses by Clinical Practice Specialty. When activities are analyzed by clinical practice specialty only those RNs with the specialty of mental

health and public health spent less than 50% of their time in direct patient care (see Table 4.6). Nurses in both of these specialties also indicated over 10% of their time was spent in professional development or training. Those RNs with the highest percentage in direct patient care were nurses with specialties in critical care/emergency room/operating room, and obstetrics. Public health nurses averaged 49.3% of their time in nursing related non-patient activities. No data for employment activities by clinical practice specialty was included in the 1996 Illinois report.

Work Environment. As can be seen in Figure 4.3 nurses select their primary nursing position for a variety of reasons. Over 65% of nurses identified a specific experience or specialization as an important factor in job choice. This factor and another frequently selected factor, geographic location, are not within the control of the employer and may be related to personal characteristics of the nurse. However, work schedule was identified by over 55% of RNs as important in job selection. This factor might suggest to employers that maintaining flexibility in scheduling is important. Salary and benefits were identified by approximately 25% of the respondents as their reason for job selection. Male respondents were more likely (34.6%) than females (24%) to identify salary and benefits as important. Other gender differences existed in the categories of work schedule (M=40.8%, F= 56.2%) and promotional opportunities (M=12.1%, F=7%). Other personal characteristics were not examined as variables, since age, income, and number of children vary over the number of years the nurse is employed; thus, these factors do not directly relate to choice of a nursing position made several years earlier.

Figure 4.3

Frequency of Responses for Job Selection

Note. Percents do not total 100% as respondents could select more than one choice.

Willingness to Work Additional Hours. In an effort to determine if those RNs employed on a part-time basis (less than 32 hours per week) would be willing to assume more work hours, all respondents were queried about the conditions under which they would be willing to work additional hours. Table 4.7 provides a comparison of RNs employed full time and part-time on conditions under which they would be willing to work additional hours. As indicated in the table, approximately one-quarter of the RNs would not be willing to increase work hours under any conditions. Note that there was little difference based on employment status.

Of the 75% of the RNs willing to increase work hours, increased salary is clearly the top incentive. RNs working part-time report an average number of hours worked of 20.3, so it would not be unreasonable to assume that as a group they could be more fully employed. Since RNs employed full time report working an average of slightly over 40 work hours a week in their primary position, the question arises about the actual number of additional hours this group would be capable of working. However, it is possible that a significant portion of the responses of the fully employed came from the 25% of RNs working 32-39 hours per week.

When exploring willingness to work by the demographic variables of gender, marital status, and gross household income, data reflect the response from the sample (see Table 4.8). In all categories higher salary continues to be the primary incentive for working additional hours. As might be expected, females are more likely than males to decline additional work hours; 24% of women and 18.9 % of men would not increase their employment status. Similarly, as gross household income increases, there is a trend toward less willingness to work additional hours regardless of the incentive.

The definite preference for higher salary was further substantiated when respondents were asked how satisfied they are with their current salary. Over one-third were somewhat dissatisfied (23.7%) or very dissatisfied (10.4%) with their nursing salary (see Table 4.9). Since staff nurses comprise the largest portion of the sample their responses tend to skew the data toward less satisfaction with nursing salary. Those RNs functioning as nurse executives, nurse practitioners, nurse anesthetists, nurse midwives, consultants, and clinical nurse specialists are more satisfied with their salary. A breakdown of satisfaction with nursing salary by primary nursing position is provided on Table 4.10.

Annual Earnings of RNs. Rather than solicit specific hourly wage RNs were asked to indicate their annual income categories for their primary nursing position. A summary of earnings from primary position is provided in Figure 4.4. The median salary range falls between \$35,001 and \$50,000 with 41.3% of RNs reporting a salary within this range. Nursing salaries in Illinois continue to have a narrow range with 85% of all salaries falling between \$25,001 and \$75,000. The lowest reported salary is for office nurses, with over half reporting an annual salary of \$35,000 or less. Among the highest paid nurses are advanced practice nurses and nurse executives. Forty-percent of nurse executives earn more than \$75,001 annually. Among advanced practice nurses, 72% of nurse practitioners earn between \$50,001 and \$75,000. The highest paid RNs are the nurse anesthetists; 92% report earning an annual salary over \$75,001 with 51% earning between \$100,001-\$150,000. Nurse anesthetists were also the highest paid RNs in

Illinois in 1996, reporting an annual income of \$72,000. See Table 4.11 for salary related to specific nursing positions.

Figure 4.4

Annual Income from Nursing Position for Full-time RNs

N= 4600

Job Satisfaction

Satisfaction with Nursing Position. Registered nurses seem to be more satisfied with their nursing position than their nursing salary. Of those responding, 83.9 % were very satisfied or somewhat satisfied with their nursing position (Table 4.12). In comparison, only 58.4% were very satisfied or somewhat satisfied with their nursing salary (Table 4.9). Those nurses most satisfied with their nursing position earned the highest salaries. Satisfaction with position by income was lowest for those earning between \$15,001 - \$25,000 (Table 4.13). However, for all RNs earning below \$75,000, over 82% were very satisfied or somewhat satisfied with their nursing position.

Figure 4.5

Satisfaction with Nursing Position by Income of Position

N = 6318

When satisfaction with nursing position was examined by the type of position (staff nurse, office nurse, etc.), at least 80% of respondents in all categories indicated some degree of satisfaction with their position (see Table 4.14). Advanced practice nurses appear to be most satisfied with their position; with the exception of nurse midwives, over 50% responded they were very satisfied with their position. Staff nurses are the most dissatisfied with their nursing position, with 18.9% indicating some degree of dissatisfaction.

Satisfaction within Setting. Exploring satisfaction with nursing setting revealed that RNs working in educational settings, community health settings, and medical group practices are among the most highly satisfied with their position (Table 4.15). It is difficult to determine why these settings are more satisfying to RNs but perhaps these are areas where the greatest level of independence and autonomy is possible. Settings in which nurses report the least satisfaction with their position are nursing homes and hospitals. Nurses who are self-employed have higher percentages of satisfaction and those in nursing pools appear to be more dissatisfied; however, there are too few respondents in these categories to make generalizations.

Satisfaction by Practice Specialty. Satisfaction with nursing position was also examined by type of practice specialty. These data are provided on Table 4.16. Across all practice specialties over 75% of RNs are satisfied with their nursing position. School nurses and public health nurses were most satisfied with their practice specialty. Least

satisfied were those RNs who practice medical-surgical and mental health nursing. Without exploring these data by setting and position further generalizations are not warranted.

Demographics. Demographic variables that could affect satisfaction with primary nursing position were analyzed and are presented in Table 4.17. Gender differences were minimal; males were slightly less satisfied with their nursing position than females. White non-Hispanics indicated the highest degree of satisfaction. African American/Blacks were the least satisfied with their primary nursing position. Whether this disparity is a function of career choice, setting, salary, or other variables needs future exploration.

How satisfied RNs are with their primary position appears to increase with age. Of those less than 30 years only 27.3% were very satisfied while of those 46-65, years 40% were very satisfied. Likewise over 23% of the very youngest nurses reported some degree of dissatisfaction with their position. It is possible that younger nurse's opinions of their position reflect their entry-level status. Therefore, they are more likely to hold entry-level positions, work alternating shifts, and lack the education required for advanced practice positions.

Table 4.1

Percentage of RNs Reporting Years Employed as an RN Across Four Surveys

Years Employed	1988 %	1992 %	1996 %	2000* %

>65 years	117	62.4	34.2	.09	2.6

Note. Results are expressed as percentage of RNs reporting satisfaction by demographics, e.g., 39.5% of 6293 females reported they were very satisfied with their primary position.

CHAPTER 5

EDUCATIONAL PATTERNS OF ILLINOIS REGISTERED PROFESSIONAL NURSES

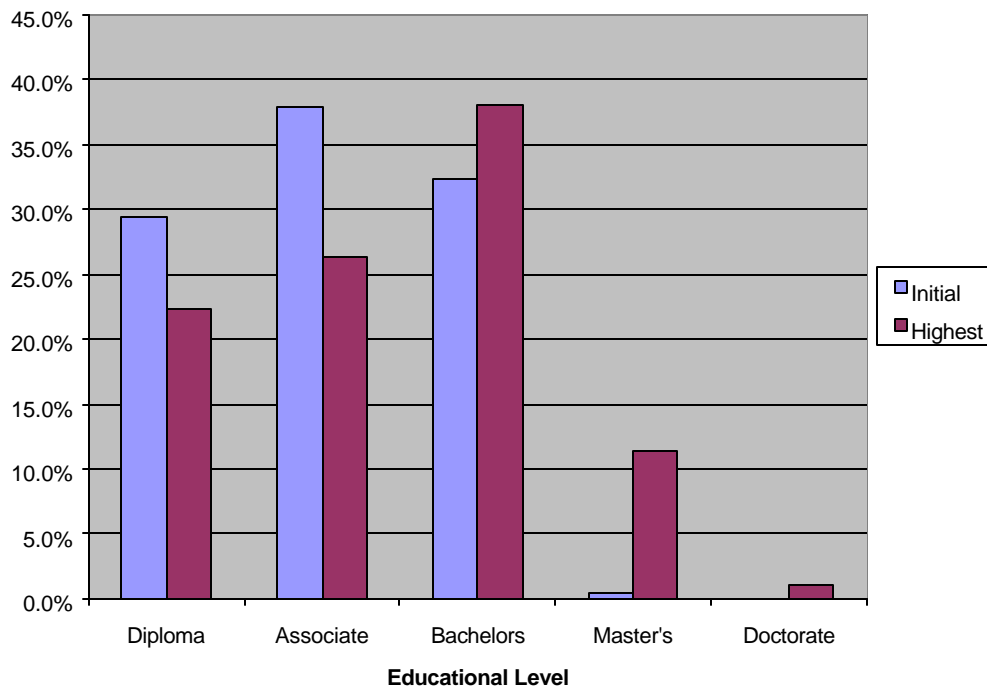

This chapter describes the initial education, highest level of degree attainment, current enrollment in formal education, and continuing education of those nurses who are currently working in Illinois. A comparison of highest educational attainment across the seven surveys from 1986-2000 is shown in Chapter 2, page 2.1. Baccalaureate RNs in the Year 2000 data continue their steady increase as the greatest proportion of nurses when highest degree attainment is examined. A steady decrease in the proportion of those reporting diploma education as their terminal degree is also of note.

Initial Education and Highest Levels of Educational Attainment

Below, Figure 5.1 graphically depicts both initial and highest levels of education reported by RNs in the Year 2000 survey. Although more nurses report associate degrees (37.9%) as their initial level of education, more nurses report the bachelor's degree (39.4%) as their highest level of education. Approximately 7% more RNs report a bachelor's degree as their highest level of education than as their basic degree.

Figure 5.1

Comparison of Initial and Highest Educational Levels of RNs Employed in Illinois in 2000

Employment Location. Table 5.1 and 5.2 present initial and highest levels of educational attainment by current employment location. Levels of education vary greatly throughout the state. The percentage of nurses educated originally at the baccalaureate level or above ranges from highs of approximately 50% in the city of Chicago to lows of 10% in other portions of the state. Similarly, the percentage of nurses whose highest levels of educational attainment are baccalaureate and above range from a low of approximately 25% to a high of 66%. HSAs 2 and 10 contain the highest concentrations of RNs with diplomas as their basic education. HSA 5 contains the highest concentration (71.3%) of RNs first educated as ADNs. Approximately half of all nurses in HSA 6 were educated originally at the baccalaureate level. As in past surveys, HSAs 5 and 6 have the highest concentrations of baccalaureate and master's prepared nurses, HSA 10 the least concentration. HSA 5 is the only area in which a majority of RNs report an associate degree as highest level of attainment.

Position, Practice Specialty, and Setting. Variations in primary nursing position, clinical practice specialty, and clinical setting by basic education program are shown in Tables 5.3-5.5. More nurse faculty, advance practice nurses, and nurse executives list their initial education as a baccalaureate degree than RNs in other nursing positions. The largest proportion of nurses in most clinical practice specialties began their education in associate degree programs. The occupational health setting contains the fewest nurses originally prepared at the baccalaureate level (18.3%); nursing education the most (48.0%).

Variations in primary nursing position, clinical specialty, and clinical setting by highest degree attained are shown in Tables 5.6-5.8. As they have in the past, Illinois nurses whose highest level of education is a diploma constitute the largest percentage of office nurses (33.5%). In all other nursing positions, the highest concentration of nurses is prepared at the baccalaureate or master's level. The majority of nurse faculty (50.8%) and advanced practice nurses (62.5%) are master's prepared. Settings with a high proportion of nurses (>60%) prepared at the baccalaureate level and beyond are schools (K-12), nursing education programs, and community/public health.

Approximately 50% of nurses in most of the practice specialties are educated at the baccalaureate level or higher. Geriatric nurses and generalists (nurses reporting no specialty) have significantly lower levels of education, 35.0% and 42.4% respectively. Public health nurses and school nurses have higher levels of education than other specialties. The RN workforce in both specialties is well over 60% baccalaureate and/or master's prepared.

Satisfaction. Satisfaction with position does not appear to vary greatly by initial educational program or by highest educational degree attained (Tables 5.9 and 5.10). Satisfaction with position by highest degree attained ranges between 81-88%. AD graduates report lowest levels of satisfaction; master's and doctorally prepared RNs report the highest. Diploma, master's, and doctorally prepared RNs are most likely to report being very satisfied with their positions.

Regardless of type of basic educational program or highest level of educational attainment, the majority of nurses are satisfied with their salaries (Tables 5.11 and 5.12). However, nurses with more education (master's and doctorally prepared) are

approximately twice as likely as their less educated counterparts to report being very satisfied with their salaries.

Current Enrollment for Academic Degree

The percentage of RNs enrolled in a formal academic degree program continues to gradually decline from a high of 13.7% in 1986 to the current rate of 9.6%. This rate shows only slight variation by HSA (Table 5.13); however, rates of enrollment vary greatly by principal nursing position, clinical specialty, and employment setting (Tables 5.14-5.16). Nurses whose primary positions are staff/patient educators or nurse managers have the highest rates of current enrollment, 14.2% and 14.6% respectively. Office nurses and case managers report the lowest rates-- 4.5% and 6.9%. Nurses with clinical specialties in mental health report significantly higher rates of enrollment (15.8%) than those working in other clinical sites. Geriatric nurses and nurses identifying themselves as generalists with no clinical specialty report the lowest rates of enrollment, 6.0% and 6.3% respectively. Nurses employed in education, schools, hospitals, and community/public health settings report the highest rates of enrollment—10-12%.

A slight majority of those returning to school for a formal degree (56.4%) are seeking a baccalaureate degree; another 38.6% are seeking a master's degree (Figure 5.2). However, not all of these returning RNs are seeking a professional nursing degree. Approximately 40% of those returning are seeking a baccalaureate degree in nursing and 26% a master's in nursing.

Figure 5.2

Current Enrollment by Degree Type

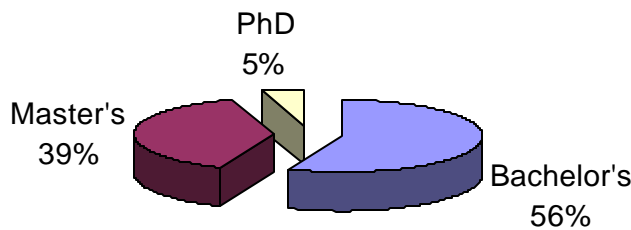

Table 5.17 presents current enrollment by highest level of educational attainment. RNs whose highest level of educational attainment to date is an associate degree report the highest proportional rates of enrollment. Diploma nurses report the lowest.

Continuing Education

Participation of nurses employed in Illinois in continuing education within the past year is shown in Tables 5.18-5.23. The portion of RNs participating in continuing education has remained fairly consistent since 1986. Approximately 89% of nurses in the Year 2000 report participation in some type of continuing education program. The majority of these report less than 20 hours of such education. Across Illinois HSAs continuing education participation varies slightly from 87.2% to 93.0%.

Participation in continuing education shows greater variance by primary nursing position, ranging from lows of 78.5% among staff nurses to highs of 96.4% among advanced practice nurses (Table 5.20). Nurses who view themselves as generalists (report no specialty) and geriatric nurses are least likely to participate in continuing education; critical care nurses and obstetrical nurses most likely (Table 5.21). Just as those who report geriatrics as their specialty are least likely to have continuing education hours, so, too, are those who report their employment setting as nursing homes (80%) (Table 5.22). RNs who work in nursing education, hospitals, home health, occupational health, and community/public health settings all report fairly high levels of continuing education—approximately 90-92%. When continuing education is examined by highest degree of education attained, master's and doctorally prepared nurses consistently report more continuing education than their less educated counterparts (Table 5.23).

Selected Demographics and Education. The last four tables (5.24-5.27) are discussed together here to more clearly highlight patterns in all areas of education. Proportionately more nurses who are male report baccalaureate degrees, both as their initial degrees and as highest degree attained. They also report higher proportions of current enrollment and continuing education participation. In terms of initial education, proportionately more nurses who are African American or Hispanic and aged 30-45 started their careers as ADN. The largest portion of the African American nurse workforce also report ADN as highest degree attained. In contrast, proportionately more Hispanic nurses report the baccalaureate degree than the ADN degree as highest degree earned. However, proportionately, African Americans comprise the largest group of RNs currently enrolled in formal education; African Americans are twice as likely to be currently seeking additional formal education as Hispanic and white non-Hispanic RNs. The proportion of nurses participating in continuing education does not vary greatly by race/ethnicity.

Across all age groups and regardless of number of children, the baccalaureate degree is the most frequently reported highest degree attained. Proportionately, more married and single women report their highest degree as a baccalaureate; those who are widowed/divorced/separated are most likely to have attained only associate degrees. A greater proportion of single RNs are currently enrolled in formal education than their married or sometimes married counterparts. A slightly higher proportion of RNs with gross household incomes between \$25,001 and \$35,000 report an associate degree as highest level of education; for all other income groups the baccalaureate degree is the most frequently cited. Proportionately fewer women whose children are 5 years of age or younger currently participate in formal or continuing education. However, this proportion varies little by number of children. Persons with gross household incomes

below \$25,000 (a very limited number of RN household; n=245) report proportionately less participation in formal or continuing education than their wealthier counterparts. Finally, a quarter of the nursing workforce reported plans to enter a formal educational program to increase their skills in the next three years.

Table 5.1**Initial Educational Preparation by Current Employment Location**

Employment Location	Number	Level of Initial Education			
		Diploma %	Associate %	Bachelor's %	Master's %
HSA 1	377	36.3	43.8	19.6	0.3
HSA 2	538	41.3	39.0	19.3	0.4
HSA 3	392	37.0	38.0	25.0	0.0

CHAPTER 6

ADVANCED PRACTICE NURSES (APNS)

The Year 2000 Survey is the first survey to contain a section specific to APNs. This new chapter reports the results of that section. The number of APNs in Illinois has increased as the state and federal government have focused increased attention on improving access and availability of health care. APNs include nurse practitioners, clinical nurse specialists, nurse midwives, and nurse anesthetists. Of **all** sampled registered nurses renewing their licenses in 2000, approximately 7.7% were educated as APNs and 7.3% were currently practicing as APNs. Of those educated as APNs (n=700), 58.7% were practicing as APNs, and 67.9% were nationally certified in their specialty area. Another 25.7% were not nationally certified but were new graduates within the last year. Of those employed, but not currently practicing as APNs, the following reasons were given: 11.1% were satisfied with current job, 6.0% had better salary/benefits in current non-APN job, and 5.7% found it difficult to get APN position. Another 10.9% listed other reasons, e.g. new graduate, position eliminated, family responsibilities, teaching/research position, returned to school for another degree.

Of those sampled registered nurses who are **currently employed** in Illinois, a slightly lower percentage--7.2% were educated as APNs (n=488). Of these approximately 2/3 are currently practicing as APNs. The following sections describe these practicing APNs. Because APNs currently employed in Illinois constitute such a small percentage of the overall sample, subdivisions of this data must be viewed with caution. The authors have provided only major subcategories of data.

Demographics

The majority of APNs are female (86.4%), white non-Hispanic (92.2%), married (75.2%), with two or more children (63.7%). The mean age of APNs at time of survey was 45.03. The majority of APNs employed full-time report salaries of greater than \$50,000 (81.6%) and 51.7% earn between \$50,000 and \$75,000. Approximately 92.9% of APNs report a gross annual household income for 1999 of greater than \$50,000, and approximately 2/3 report a gross annual household income of greater than \$75,000.

Professional Work History, Education, and Certification

The majority of APNs (two-thirds) have 10 or less years of experience (Table 6.1). Fully 15% have one year or less. Approximately 83.3% are nationally certified in their specialty area, and 12.9% are not certified but have graduated within the last 12 months.

Over two-thirds of nurses educated as APNs report earning a master's (66.6%) or doctoral degree (4.9%). Approximately half of all doctorally prepared nurses and half of all master's prepared RNs are APNs. These same percentages apply to those nurses currently practicing as APNs.

Twenty-three percent of APNs working in Illinois reported that they encountered difficulty finding their current APN job. The number one reason specified for this

difficulty was lack of jobs for APNs in desired geographic location (38.8%), followed by overall lack of practice opportunities for APNs (29.9%), and lack of jobs for APNs in desired practice setting (19.4%).

Practice Patterns

Of those RNs educated as APNs and practicing in Illinois, 37.6% describe themselves as nurse practitioners, 19.9 % as anesthetists, 18.3% as clinical nurse specialists, and 7.6% as midwives. An additional 16.5% of APNs are currently practicing in other positions, i.e, faculty, nurse consultant. Figure 6.1 depicts Illinois' practicing APN workforce by APN specialty. Nurse practitioners constitute the majority of this APN workforce (45%).

Figure 6.1

Illinois RNs Practicing as APNs by APN Specialty

N = 314

The hospital is the most frequently listed APN employment setting (42.2%). Another 37.3% of APNs practice in a clinic or private/group medical practice. Among other types of APN practice settings cited are nursing education, community/public health, and self-employment. Approximately 75% of APNs practice in a major metropolitan area. Of these 75%, one-third practice in the inner city. Only a small portion of APNs are employed in a federally designated rural health clinic. The majority of APNs are salaried (no incentive) and practice with a physician on site for more than 32 hours a week. Describing their current practice, the vast majority of APNs are accepting new patients and provide care to Medicaid patients.

An overwhelming majority of APNs (90.1%) are satisfied with their positions—52.9 are very satisfied; 37.2% somewhat satisfied. A somewhat lesser number are satisfied with their salaries—28.2% very satisfied; 45.6% somewhat satisfied.

The researchers recognized the importance of gathering baseline information on this group prior to the implementation of the recent legislative changes in Illinois licensure. In future years as the climate for APN practice changes, it will be interesting to follow changes in this vital section of the Illinois APN workforce.

APPENDIX B
SURVEY INSTRUMENT

Due to technical difficulty the survey instrument is not available at this time.

**APPENDIX C
1996 NURSING
PRACTICE
SPECIALTIES BY
EMPLOYMENT
LOCATION**

1996 Nursing Practice Specialty by Employment Location (HAS)

Employment Location		1	2	3	4	5	6	7	8	9	10	11	Total
Specialty	N	2034	2510	1981	2291	1804	6312	9550	2884	1337	630	1369	32702
Orthopedics		5.5	6.7	6.0	5.6	7.4	5.7	6.5	7.0	5.8	7.1	7.8	6.3
Administration		8.8	10.0	10.2	10.6	12.2	10.5	8.8	10.1	8.8	10.2	9.9	9.8
Geriatrics		17.8	20.3	18.9	21.0	25.6	11.3	14.7	15.6	18.7	19.2	21.6	16.6
Medical		24.5	27.7	28.4	25.4	33.3	27.6	26.6	23.5	30.4	26.5	30.7	27.2
Surgical		21.8	27.3	26.5	21.4	29.5	26.3	25.7	22.2	26.0	23.7	32.4	25.6
Obstetrics		11.0	10.7	11.4	10.0	10.4	10.8	10.9	12.4	12.9	11.0	10.1	11.0
Pediatrics		11.5	11.2	9.5	10.3	10.3	16.0	11.4	10.9	11.1	11.9	9.5	11.9
Psychiatric		5.9	6.2	7.0	5.5	8.0	6.7	5.8	7.8	6.9	5.2	8.0	6.5
Public Health		12.0	10.3	12.4	12.5	15.7	8.3	8.2	9.2	10.2	15.4	10.5	10.0
Other		34.7	32.0	30.7	36.2	27.3	33.7	36.0	37.3	32.0	31.3	32.4	34.1

Note Results are expressed as percentages, e.g., 5.5% of 2,034 RNs employed in Health Service Area 1 reported a practice specialty in Orthopedics. Results within HSAs do not sum to 100% due to the multiple response format (i.e., nurses may list more than 1 practice specialty).
